An Ocean of Plastic

Ocean currents have been carrying floating debris into all five of the world's major oceanic gyres for decades. The rotating currents of these so-called "garbage patches" create vortexes of trash, much of it plastic. However, exactly how much plastic is making its way into the world's oceans and from where it originates has been a mystery — until now.

A new study published today in the journal *Science*, quantifies the input of plastic waste from land into the ocean and offers a roadmap for developing ocean-scale solutions to the problem of plastic marine pollution. The research was conducted by a scientific working group at UC Santa Barbara's National Center for Ecological Analysis and Synthesis (NCEAS) with support from the Washington, D.C.-based Ocean Conservancy. To conduct the research, lead author Jenna Jambeck, an environmental engineer at the University of Georgia, coordinated contributions from experts in oceanography, waste management and plastics materials science.

The study found that more than 4.8 million metric tons of plastic waste enter the oceans from land each year, and that figure may be as high as 12.7 million metric tons. That's one to three orders of magnitude greater than the reported mass of plastic floating in the oceans. A metric ton is equivalent to 1,000 kilograms or 2,205 pounds.

"Using the average density of uncompacted plastic waste, 8 million metric tons — the midpoint of our estimate — would cover an area 34 times the size of Manhattan ankle-deep in plastic waste," said co-author Roland Geyer, an associate professor at

the Bren School of Environmental Science & Management. “Eight million metric tons is a vast amount of material by any measure. It is how much plastic was produced worldwide in 1961.”

Previous studies have documented the impact of plastic debris on more than 660 marine species — from the smallest of zooplankton to the largest whales, including fish destined for the seafood market — but none have quantified the worldwide amount entering the ocean from land. “This is the first time people have connected the dots in a quantifiable way,” said Jambeck.

According to the study, countries with coastal borders — 192 in all — discharge plastic into the world’s oceans with the largest quantities estimated to come from a relatively small number of middle-income, rapidly developing countries. In fact, the investigators found that the top 20 countries accounted for 83 percent of the mismanaged plastic waste available to enter the ocean. They went on to say that reducing the amount of this waste by 50 percent would result in a nearly 40 percent decline in inputs of plastic to the ocean.

“Large-scale removal of plastic marine debris is not going to be cost-effective and quite likely simply unfeasible,” said Geyer. “This means that we need to prevent plastic from entering the oceans in the first place through better waste management, more reuse and recycling, better product design and material substitution.”

Knowing how much plastic is going into the ocean is just one part of the puzzle. Millions of metric tons reach the oceans, yet researchers are finding between 6,350 and 245,000 metric tons floating on the surface — a mere fraction of the total. This discrepancy is the subject of ongoing research.

“Right now, we’re mainly measuring plastic that floats,” said study co-author Kara Lavender Law, a research professor at the Massachusetts-based Sea Education Association. “There is a lot of plastic sitting on the bottom of the ocean and on beaches worldwide.”

The NCEAS working group forecasts that the cumulative impact to the oceans could be as high as 155 million metric tons by 2025. However, the planet will not reach global “peak waste” before 2100, according to World Bank calculations. “We’re being overwhelmed by our waste,” Jambeck said.

“The numbers are staggering, but as the group points out, the problem is not insurmountable,” said NCEAS Director Frank Davis, who is also a professor at the Bren School. “The researchers suggest achievable solutions that could reverse the alarming trend in plastics being dumped into our oceans.”

Among them, according to the study, are waste reduction and “downstream” waste management strategies such as expanded recovery systems and extended producer responsibility. According to the researchers, while infrastructure is being built in developing nations, “industrialized countries can take immediate action by reducing waste and curbing the growth of single-use plastic.”

About UC Santa Barbara

The University of California, Santa Barbara is a leading research institution that also provides a comprehensive liberal arts learning experience. Our academic community of faculty, students, and staff is characterized by a culture of interdisciplinary collaboration that is responsive to the needs of our multicultural and global society. All of this takes place within a living and learning environment like no other, as we draw inspiration from the beauty and resources of our extraordinary location at the edge of the Pacific Ocean.
