Finding Middle Ground on the Range

Cattle ranching and conservation may seem an unusual pair in the American West, but new research reveals a clear link between the economic health of ranches and the ability to maintain habitat for an iconic wild bird that for years has been at the center of public land policy debate: the greater sage grouse.

A study led by UC Santa Barbara's [National Center for Ecological Analysis and Synthesis \(NCEAS\)](#) shows that policies to restrict grazing access on public lands may have the unintended consequence of exacerbating sage grouse habitat loss. Such restrictions are likely to harm ranch profitability, which in turn could spur ranchers to sell their private lands for other uses — namely, crop cultivation or housing developments — that would ultimately destroy critical grouse habitat.

The paper, "[Unintended habitat loss on private land from grazing restrictions on public rangelands](#)" is published in the *Journal of Applied Ecology*

"When it comes to a choice between ranching, farming or housing in the West, sustainable ranching is the most compatible with wildlife," said lead author Claire Runge, who was a postdoctoral researcher at NCEAS when the research was conducted and is now a research scientist at the University of Tromsø – The Arctic University of Norway. "Implementing policy that makes it harder for ranchers to keep going could result in land conversions that are bad news for sage grouse and other sagebrush species."

Runge stressed that ranchers must still practice sustainable grazing to support habitat for grouse and to maintain forage availability for their cattle. Moreover, the findings demonstrate that public and private lands are inextricably linked.

Sage grouse rely on both public and private lands throughout their lifecycles. More than half of their total habitat is on public lands, which include the dry sagebrush uplands where they breed, nest and overwinter.

In fact, while sage grouse are not listed as an endangered species, they are considered the canary in the coal mine for sagebrush ecosystems, which are home to more than 350 other plant and animal species.

“If you have sage grouse, you have intact, healthy sagebrush habitat,” said co-author David Naugle, a professor at the University of Montana and science advisor for the U.S. Department of Agriculture’s Natural Resources Conservation Service Working Lands for Wildlife.

In the summer, the grouse rely on productive, private ranchlands for 75 percent of the lower, wetter habitat they need for raising and feeding their chicks. Losing these private lands to crops or subdivisions would threaten chick survival, which can make or break many grouse populations.

As the saying goes — and as this study shows — what’s good for the bird is also good for the herd. Ranchers also rely on public and private lands for forage, and curtailed grazing on public lands limits available forage. According to the study, these restrictions could strain ranch profitability and eventually force ranchers to sell their lands to those more profitable pursuits that are not suitable for sage grouse.

“By keeping people ranching, we get wins for those communities — they’re healthier and more vibrant — and we get a win for conservation, because we get healthy rangelands and healthy populations of sage grouse,” said Runge.

Sage grouse are already experiencing a “slow drip” of habitat loss due to land conversions, which is just one of several threats the birds face. Restricting grazing would add to this slow drip — the authors calculate that curbing grazing on public land by 50 percent could result in a loss of over 429,000 acres of grouse habitat by 2050, in addition to the 2.1 million-acre loss expected even if grazing goes unrestricted.

The results indicate the importance of anticipating how public land policies intended to conserve biodiversity will affect people, especially ranchers, and the choices they might make for their private lands as a result.

“Every action has a reaction, and when you change something on public lands, it influences private lands and vice versa,” said Naugle.

According to co-author Joe Fargione, science director for The Nature Conservancy’s North American region, the researchers’ findings validate the increasing recognition that ranchers and conservationists must partner to support healthy sagebrush ecosystems for cattle and sage grouse, and open the door to creative solutions that take a more balanced approach.

“There is a middle ground,” said Fargione. “Public policy should manage to protect resources on public lands, while also supporting ranchers in their stewardship of habitat on both public and private lands for the West’s iconic wildlife.”

This study was supported by the [Gordon and Betty Moore Foundation](#) and the [Science for Nature and People Partnership](#), a collaboration between NCEAS, The Nature Conservancy and Wildlife Conservation Society.

About UC Santa Barbara

The University of California, Santa Barbara is a leading research institution that also provides a comprehensive liberal arts learning experience. Our academic community of faculty, students, and staff is characterized by a culture of interdisciplinary collaboration that is responsive to the needs of our multicultural and global society. All of this takes place within a living and learning environment like no other, as we draw inspiration from the beauty and resources of our extraordinary location at the edge of the Pacific Ocean.
